AB A novel method for detecting LDL and denatured LDL (particularly, **oxidized LDL**) having a significant concern with the onset and progression of arteriosclerosis and Alzheimer's disease is provided, wherein a complex of denatured LDL (particularly, **oxidized LDL**) with an acute phase reactant, blood coagulation-fibrinolytic-related protein or disinfectant substance produced by macrophage is used as a measuring subject. Human LDL free of .alpha.1 antitrypsin and human fibronectin were treated with a copper sulfate soln. at 37.degree. over night to form an **oxidized LDL**-fibronectin complex. The complex was used as an immunogen in a mouse from which monoclonal **antibodies** were prepd. for use in assaying for the complex.

AB **Antibodies** against malondialdehyde (MDA)-modified proteins are often increased in patients with diseases related to oxidative stress. However, the clinical significance of these **antibodies** is hampered by their frequent presence also in healthy controls. Aim of this work has been to characterize the immune reactivity against MDA-derived antigens in healthy subjects. The sera of 120 healthy subjects contained IgG and IgM targeting MDA-modified human albumin (HSA), **fibrinogen**, and LDL. These sera also displayed weak reactivity with **oxidized LDL** and HSA complexed with oxidized arachidonic acid. Conversely, oxidized HSA or HSA complexed with other aldehydic lipid peroxidation products was not recognized. Control sera also did not recognize cyclic dihydropyridine-MDA products, while HSA-MDA reactivity was associated ($r > 0.9$; $p < .0005$) with the presence of fluorescent lysine-conjugated-imine cross-links. In Western blots both IgG and IgM recognized high molecular weight HSA-MDA aggregates, but not monomeric HSA-MDA adducts. The addition of sodium cyanoborohydride, that prevented conjugated-imine fluorescence and protein aggregation during HSA-MDA preparation, abolished the

AB We investigated the effects of two well established risk factors for cardiovascular disease, homocysteine and oxidized low density lipoprotein (**ox-LDL**), on endothelial cell thrombogenicity. For this purpose we studied platelet adhesion to human endothelial cells (EC) under flow conditions at a shear rate of 350 s-1 following EC treatment with either homocysteine or **ox-LDL**. Treatment of EC with either homocysteine (1 or 10 mmol/L for 16 h) or **ox-LDL** (100 mug/ml for 16 h) resulted in a 2-3 fold enhancement in platelet adhesion. The enhancement in platelet adhesion induced by 1 mmol/L homocysteine, but not that induced by 10 mmol/L homocysteine, was absolutely dependent on fibrin formation. Homocysteine treatment has significantly increased the cell surface tissue factor (TF) activity and slightly reduced the expression of the intercellular adhesion molecule I (ICAM-1). In contrast, **ox-LDL** treatment upregulated ICAM-1 expression and had no significant effect on endothelial TF activity. Neither homocysteine nor **Ox-LDL** affected surface expression of the alphavbeta3 integrin. The homocysteine-induced enhancement in platelet adhesion was almost completely abolished by blockade of the EC TF activity by a polyclonal **antibody**. The enhancing effect of homocysteine was also greatly reduced by inhibition of the EC alphavbeta3 integrin, but was not affected by blockade of EC ICAM-1. On the other hand, **ox-LDL**-induced enhancement in platelet - EC adhesion was greatly inhibited by blocking ICAM-1 or alphavbeta3, but remained unaffected by inhibition of TF activity. Preincubation of platelets with the glycoprotein IIb-IIIa (GPIIb-IIIa) antagonist Reo-Pro has virtually abolished the enhancing effect of both homocysteine and **ox-LDL**. Our results suggest that homocysteine and **ox-LDL** might increase endothelial thrombogenicity by distinct mechanisms: homocysteine - by inducing TF activity, and **ox-LDL** - by upregulating ICAM-1, both of which enhance GPIIb-IIIa/**fibrinogen** dependent platelet adhesion to EC. The alphavbeta3 integrin, although not affected by EC stimulation, seems to play a crucial role in platelet-EC interaction regardless of the mechanism of EC perturbation.

AB Although important roles of dietary n-3 fatty acids in the prevention of coronary heart disease (CHD) have been suggested, long-term effects of dietary alpha-linolenic acid (ALA, 18:3n-3) have not yet been established under controlled conditions. We tested whether a moderate increase of dietary ALA affects fatty acids composition in serum and the risk factors of CHD. **Oxidized LDL** (OxLDL) was directly measured by ELISA using **antibody** specific to OxLDL. By merely replacing soybean cooking oil (SO) with perilla oil (PO) (i.e., increasing 3 g/d of ALA), the n-6/n-3 ratio in the diet was changed from 4: 1 to 1 : 1. Twenty Japanese elderly subjects were initially given a SO diet for at least 6 mo (baseline period), a PO diet for 10 mo (intervention period), and then returned to the previous SO diet (washout period). ALA in the total serum lipid increased from 0.8 to 1.6% after 3 mo on the PO diet, but EPA and DHA increased in a later time, at 10 mo after the PO diet, from 2.5 to 3.6% and 5.3 to 6.4%, respectively ($p < 0.05$), and then returned to baseline in the washout period. In spite of increases of serum n-3 fatty acids, the OxLDL concentration did not change significantly when given the PO diet. Body weight, total serum cholesterol, triacylglycerol, glucose, insulin and HbA1c concentrations, platelet count and aggregation function, prothrombin time, partial thromboplastin time, **fibrinogen** and PAI-1 concentration, and other routine blood analysis did not change significantly when given the PO diet. These data indicate that, even in elderly subjects, a 3 g/d increase of dietary ALA could increase serum EPA and DHA in 10 mo without any major adverse effects.

AB The modification of tyrosine residues in proteins to 3-nitrotyrosine by peroxynitrite or other potential nitrating agents has been detected in biological systems that are subject to oxidative stress. A convenient semi-quantitative method has been developed to assay nitrated proteins in biological fluids and homogenates using a competitive ELISA developed in our laboratory. This assay selectivity detected 3-nitro-L-tyrosine residues in a variety of peroxynitrite-treated proteins (BSA, human serum albumin (HSA), alpha1-antiprotease inhibitor, pepsinogen and

AB It has been suggested that the **fibrinogen** receptor (glycoprotein (GP) IIb-IIIa or platelet integrin alpha-IIb-beta-3) could be the binding site for low-density lipoprotein (LDL); however, recent data do not support this. Furthermore, GPIIb and not the GPIIb-IIIa complex is the main binding protein for lipoprotein(a) (Lp(a)). In the present study, we have investigated the interaction between Lp(a) particles and platelet LDL binding sites and whether platelet integrin alpha-IIb-beta-3 is implicated. Displacement experiments showed that 125I-LDL binding to intact resting platelets was inhibited with the same apparent affinity by both unlabeled LDL and apolipoprotein(a)-free lipoprotein particles (Lp(a)-, an LDL-like particle prepared from Lp(a)). Hill coefficients for displacement curves suggested that a single set of binding sites was involved. In contrast, both native and oxidized Lp(a) particles were unable to inhibit platelet LDL binding. Furthermore, platelets bound 125I-Lp(a)- particles to a class of saturable binding sites numbering approximately 1958+-235 binding sites per platelet with a dissociation constant (K-d) of 48.3+-12 times 10-9 mol/L. These values were similar to those obtained for LDL. In contrast to Lp(a), evidence indicates that platelet integrin alpha-IIb-beta-3 was not involved in the interaction of LDL and intact resting platelets. First, specific ligands for platelet integrin alpha-IIb-beta-3, such as **fibrinogen**, vitronectin, and fibronectin, were unable to inhibit the binding of LDL to intact resting platelets. Second, similar LDL binding characteristics (K-d and B-max values) were found in platelets from control subjects and patients with type I and type II Glanzmann's thrombasthenia, characterized by total and partial lack of GPIIb-IIIa and **fibrinogen**, respectively. Third, polyclonal **antibodies** against the GPIIb-IIIa complex (edu-3 and 5B12), human antiserums against platelet alloantigens (anti-Bak-a/B and anti-PL-A1/2), anti-integrin subunits (anti-alpha-v and anti-beta-3), and a wide panel of monoclonal **antibodies** (mAbs) against well-known epitopes of GPIIb (M3, M4, M5, M6, and M95-2b) and GPIIIa (P23-7, P33, P37, P40, and P97) did not affect platelet LDL binding. Finally, in contrast to the proaggregatory effect of native and **oxidized**

AB **Antibodies** against malondialdehyde (MDA)-modified proteins are often increased in patients with diseases related to oxidative stress. However, the clin. significance of these **antibodies** is hampered by their frequent presence also in healthy controls. Aim of this work has been to characterize the immune reactivity against MDA-derived antigens in healthy subjects. The sera of 120 healthy subjects contained IgG and IgM targeting MDA-modified human albumin (HSA), **fibrinogen**, and LDL. These sera also displayed weak reactivity with **oxidized LDL** and HSA complexed with oxidized arachidonic acid. Conversely, oxidized HSA or HSA complexed with other aldehydic lipid peroxidn. products was not recognized. Control sera also did not recognize cyclic dihydropyridine-MDA products, while HSA-MDA reactivity was assocd. ($r > 0.9$; $p < .0005$) with the presence of fluorescent lysine-conjugated-imine cross-links. In Western blots both IgG and IgM recognized high mol. wt. HSA-MDA aggregates, but not monomeric HSA-MDA adducts. The addn. of sodium cyanoborohydride, that prevented conjugated-imine fluorescence and protein aggregation during HSA-MDA prepn., abolished the **antibody** binding. This suggested that the plasma of healthy subjects contained IgG and IgM recognizing protein aggregates linked through 1-amino-3-imino-propene bridges. The function of these **antibodies** is at the moment unknown, but they might contribute to scavenging MDA cross-linked proteins.

AB The authors investigated the effects of 2 the authors ll established risk factors for cardiovascular disease, homocysteine and oxidized low d. lipoprotein (**ox-LDL**), on endothelial cell thrombogenicity. For this purpose the authors studied platelet adhesion to human endothelial cells (EC) under flow conditions at a shear rate of 350 s-1 following EC treatment with either homocysteine or **ox-LDL**. Treatment of EC with either homocysteine (1 or 10 mmol/L for 16 h) or **ox-LDL** (100 .mu.g/mL for 16 h) resulted in a 2-3-fold enhancement in platelet adhesion. The enhancement in platelet adhesion induced by 1 mmol/L homocysteine, but not that induced by 10 mmol/L homocysteine, was absolutely dependent on fibrin formation. Homocysteine treatment has significantly increased the cell surface tissue factor (TF) activity and slightly reduced the expression of the intercellular adhesion mol. I (ICAM-1). In contrast, **ox-LDL** treatment upregulated ICAM-1 expression and had no significant effect on endothelial TF activity. Neither homocysteine nor **Ox-LDL** affected surface expression of the .alpha.v.beta.3 integrin. The homocysteine-induced enhancement in platelet adhesion was almost completely abolished by blockade of the EC TF activity by a polyclonal **antibody**. The enhancing effect of homocysteine was also greatly reduced by inhibition of the EC .alpha.v.beta.3 integrin, but was not affected by blockade of EC ICAM-1. On the other hand, **ox-LDL**-induced enhancement in platelet-EC adhesion was greatly inhibited by blocking ICAM-1 or .alpha.v.beta.3, but remained unaffected by inhibition of TF activity. Preincubation of platelets with the glycoprotein IIb-IIIa (GPIIb-IIIa) antagonist Reo-Pro has virtually abolished the enhancing effect of both homocysteine and **ox-LDL**. These results suggest that homocysteine and **ox-LDL** might increase endothelial thrombogenicity by distinct mechanisms: homocysteine - by inducing TF activity, and **ox-LDL** - by upregulating ICAM-1, both of which enhance GPIIb-IIIa/ **fibrinogen** dependent platelet adhesion to EC. The .alpha.v.beta.3 integrin, although not affected by EC stimulation, seems to play a crucial role in platelet-EC interaction regardless of the mechanism of EC perturbation.

CC 9-10 (Biochemical Methods)
AB The modification of tyrosine residues in proteins to 3-nitrotyrosine by peroxynitrite or other potential nitrating agents has been detected in biol. systems that are subject to oxidative stress. A convenient semi-quant. method has been developed to assay nitrated proteins in biol. fluids and homogenates using a competitive ELISA developed in our lab. This assay selectivity detected 3-nitro-L-tyrosine residues in a variety of peroxynitrite-treated proteins (BSA, human serum albumin (HSA), .alpha.1-antiprotease inhibitor, pepsinogen and **fibrinogen**) and also in a nitrated peptide, but had a low affinity for free 3-nitro-L-tyrosine and 3-chloro-L-tyrosine. The IC50 values for the inhibition of **antibody** binding by different nitrated proteins were in the range 5-100 nM, suggesting that the **antibody** discriminated between nitrotyrosine residues in different environments. The presence of nitrotyrosine in plasma proteins was detected by Western blot anal. and quantified by the ELISA. A concn. of 0.12.+-.0.01 .mu.M nitro-BSA equiv. was measured in the proteins of normal plasma which was increased in peroxynitrite-treated plasma and was elevated in inflammatory

conditions. HSA and low-d. lipoprotein (LDL) isolated from plasma contained 0.085.+-.0.04 and 0.03.+-.0.006 nmol nitro-BSA equiv./mg protein, resp. Comparison of the level of nitration in peroxynitrite-treated HSA and LDL in the presence and absence of plasma indicates that nitration and presumably oxidn. is inhibited by plasma antioxidants. The presence of nitrotyrosine in LDL is consistent with previous reports implicating peroxynitrite in the oxidative modification of lipoproteins and the presence of a low concn. of **oxidized LDL** in the blood.

CC 13-5 (Mammalian Biochemistry)
AB It has been suggested that the **fibrinogen** receptor (glycoprotein IIb-IIIa or platelet integrin .alpha.IIb.beta.3) could be the binding site for low-d. lipoprotein (LDL); however, recent data do not support this. Furthermore, GPIIb and not the GPIIb-IIIa complex is the main binding protein for lipoprotein(a) [Lp(a)]. In the present study, the interaction between Lp(a) particles and platelet LDL binding sites and the role of platelet integrin .alpha.IIb.beta.3 were investigated. Displacement expts. showed that 125I-LDL binding to intact resting platelets was inhibited with the same apparent affinity by both unlabeled LDL and apolipoprotein(a)-free lipoprotein particles Lp(a)- [an LDL-like particle prepd. from Lp(a)]. Hill coeffs. for displacement curves suggested that a single set of binding sites was involved. In contrast, both native and oxidized Lp(a) particles were unable to inhibit platelet LDL binding. Furthermore, platelets bound 125I-Lp(a)- particles to a class of saturable binding sites numbering approx. 1958.+-.235 binding sites per platelet with a dissocn. const. (Kd) of 48.3.+-.12.times.10-9 mol/L. These values were similar to those obtained for LDL. In contrast to Lp(a), evidence indicates that platelet integrin .alpha.IIb.beta.3 was not involved in the interaction of LDL and intact resting platelets. First, specific ligands for platelet integrin .alpha.IIb.beta.3, such as **fibrinogen**, vitronectin, and fibronectin, were unable to inhibit the binding of LDL to intact resting platelets. Second, similar LDL binding characteristics (Kd and Bmax values) were found in platelets from control subjects and patients with type I and type II Glanzmann's thrombasthenia, characterized by total and partial lack of GPIIb-IIIa and **fibrinogen**, resp. Third, polyclonal **antibodies** against the GPIIb-IIIa complex (edu-3 and 5B12), human antiserums against platelet alloantigens (anti-Baka/B and anti-PLA1/2), anti-integrin subunits (anti-.alpha.v and anti-.beta.3), and a wide panel of monoclonal **antibodies** against well-known epitopes of GPIIb (M3, M4, M5, M6, and M95-2b) and GPIIIa (P23-7, P33, P37, P40, and P97) did not affect platelet LDL binding. Finally, in contrast to the proaggregatory effect of native and **oxidized LDL**, both native and oxidized Lp(a) particles caused a significant dose-dependent decrease of collagen-induced platelet aggregation. In conclusion, It is demonstrated that neither the GPIIb-IIIa complex nor GPIIb and GPIIIa individually are membrane binding proteins for LDL on intact resting platelets. Lp(a) particles do not interact with platelet LDL binding sites, and their biol. response is clearly different from that of LDL.

AB We measured and compared levels of platelet-derived microparticles (PMPs), monocyte-derived microparticles (MMPs), CD62P on activated platelets, soluble E-selectin (sE-selectin), and antioxidized low density lipoprotein (LDL) **antibody** in hyperlipidemia patients and control subjects. Binding of anti-GPIIb/IIIa and anti-GPIb monoclonal **antibodies** to platelets was not significantly different between hyperlipidemia patients and controls. However, expression of CD62P on platelets and levels of PMPs were higher for hyperlipidemia patients than in controls, although the difference between groups in CD62P expression was not significant (PMPs: 534 .+-. 63 vs. 388 .+-. 47, $p < 0.05$; CD62P: 9.1% .+-. 1.45 vs. 7.3% .+-. 1.15, N.S.). Although there were no differences in expression of CD36 and CD40 by monocytes between the two groups, levels of MMPs were higher in hyperlipidemia patients than in controls (MMPs: 147 .+-. 21 vs. 59 .+-. 8, respectively, $p < 0.01$). Levels of anti-**oxidized LDL antibody** and sE-selectin were also higher in hyperlipidemia patients. We studied the effects of Saiko-ka-ryukotsu-borei-to on levels of these factors in patients with elevated triglyceride levels. After Saiko-ka-ryukotsu-borei-to treatment, levels of CD62P, PMPs, sE-selectin, and anti-**oxidized LDL antibody** were reduced significantly. Levels of triglycerides, total cholesterol and MMPs also decreased, but the changes were not significant. These findings suggest that Saiko-ka-ryukotsu-borei-to prevents the development of vascular complications in hyperlipidemia patients.

However, the clinical significance of these **antibodies** is hampered by their frequent presence also in healthy controls. Aim of this work has been to characterize the immune reactivity against MDA-derived antigens in healthy subjects. The sera of 120 healthy subjects contained IgG and IgM targeting MDA-modified human albumin (HSA), **fibrinogen**, and LDL. These sera also displayed weak reactivity with **oxidized LDL** and HSA complexed with oxidized arachidonic acid. Conversely, oxidized HSA or HSA complexed with other aldehydic lipid peroxidation products was not recognized. Control sera also did not recognize cyclic dihydropyridine-MDA products, while HSA-MDA reactivity was associated ($r > 0.9$; $p < .0005$) with the presence of fluorescent lysine-conjugated-imine cross-links. In Western blots both IgG and IgM recognized high molecular weight HSA-MDA aggregates, but not monomeric HSA-MDA adducts. The addition of sodium cyanoborohydride, that prevented conjugated-imine fluorescence and protein aggregation during HSA-MDA preparation, abolished the **antibody** binding. This suggested that the plasma of healthy subjects contained IgG and IgM recognizing protein aggregates linked through 1-amino-3-imino-propene bridges. The function of these **antibodies** is at the moment unknown, but they might contribute to scavenging MDA cross-linked proteins. .COPYRGT. 2001 Elsevier Science Inc.

TI Long-term effects of dietary .alpha.-linolenic acid from perilla oil on

dietary .alpha.-linolenic acid (ALA, 18:3n-3) have not yet been established under controlled conditions. We tested whether a moderate increase of dietary ALA affects fatty acids composition in serum and the risk factors of CHD. **Oxidized LDL** (OxLDL) was directly measured by ELISA using **antibody** specific to OxLDL. By merely replacing soybean cooking oil (SO) with perilla oil (PO) (i.e., increasing 3 g/d of ALA), the n-6/n-3 ratio in the diet was changed from 4:1 to 1:1. Twenty Japanese elderly subjects were initially given a SO diet for at least 6 mo (baseline period), a PO diet for 10 mo (intervention period), and then returned to the previous SO diet (washout period). ALA in the total serum lipid increased from 0.8 to 1.6% after 3 mo on the PO diet, but EPA and DHA increased in a later time, at 10 mo after the PO diet, from 2.5 to 3.6% and 5.3 to 6.4%, respectively ($p < 0.05$), and then returned to baseline in the washout period. In spite of increases of serum n-3 fatty acids, the OxLDL concentration did not change significantly when given the PO diet. Body weight, total serum cholesterol, triacylglycerol, glucose, insulin and HbA1c concentrations, platelet count and aggregation function, prothrombin time, partial thromboplastin time, **fibrinogen** and PAI-1 concentration, and other routine blood analysis did not change significantly when given the PO diet. These data indicate that, even in elderly subjects, a 3 g/d increase of dietary ALA could increase serum EPA and DHA in 10 mo without any major adverse effects.

AB We investigated the effects of two well established risk factors for

antibody. The enhancing effect of homocysteine was also greatly reduced by inhibition of the EC .alpha.(v).beta.3 integrin, but was not affected by blockade of EC ICAM-1. On the other hand, **ox-LDL**-induced enhancement in platelet - EC adhesion was greatly inhibited by blocking ICAM-1 or .alpha.(v).beta.3, but remained unaffected by inhibition of TF activity. Preincubation of platelets with the glycoprotein IIb-IIIa (GPIIb-IIIa) antagonist Reo-Pro has virtually abolished the enhancing effect of both homocysteine and **ox-LDL**. Our results suggest that homocysteine and **ox-LDL** might increase endothelial thrombogenicity by distinct mechanisms: homocysteine - by inducing TF activity, and **ox-LDL** - by upregulating ICAM-1, both of which enhance GPIIb-IIIa/**fibrinogen** dependent platelet adhesion to EC. The .alpha.(v).beta.3 integrin, although not affected by EC stimulation, seems to play a crucial role in platelet-EC interaction regardless of the mechanism of EC perturbation.

AB The modification of tyrosine residues in proteins to 3-nitrotyrosine by peroxynitrite or other potential nitrating agents has been detected in biological systems that are subject to oxidative stress. A convenient semi-quantitative method has been developed to assay nitrated proteins in biological fluids and homogenates using a competitive ELISA developed in our laboratory. This assay selectivity detected 3-nitro-L-tyrosine residues in a variety of peroxynitrite-treated proteins (BSA, human serum albumin (HSA), .alpha.1-antiprotease inhibitor, pepsinogen and **fibrinogen**) and also in a nitrated peptide, but had a low affinity for free 3-nitro-L-tyrosine and 3-chloro-L-tyrosine. The IC50 values for the inhibition of **antibody** binding by different nitrated proteins were in the range 5-100 nM, suggesting that the **antibody** discriminated between nitrotyrosine residues in different environments. The presence of nitrotyrosine in plasma proteins was detected by Western blot analysis and quantified by the ELISA. A concentration of 0.12 .+-. 0.01 .mu.M nitro-BSA equivalents was measured in the proteins of normal plasma which was increased in peroxynitrite-treated plasma and was elevated in inflammatory conditions. HSA and low-density lipoprotein (LDL) isolated from plasma contained 0.085 .+-. 0.04 and 0.03 .+-. 0.006 nmol nitro-BSA equivalents/mg protein, respectively. Comparison of the level of nitration in peroxynitrite-treated HSA and LDL in the presence and absence of plasma indicates that nitration and presumably oxidation is inhibited by plasma antioxidants. The presence of nitrotyrosine in LDL is consistent with previous reports implicating peroxynitrite in the oxidative modification of lipoproteins and the presence of a low concentration of **oxidized LDL** in the blood.

AB It has been suggested that the **fibrinogen** receptor (glycoprotein [GP] IIb-IIIa or platelet integrin .alpha.(IIb).beta.3) could be the binding site for low- density lipoprotein (LDL); however, recent data do not support this. Furthermore, GPIIb and not the GPIIb-IIIa complex is the main binding protein for lipoprotein(a) [Lp(a)]. In the present study, we have investigated the interaction between Lp(a) particles and platelet LDL binding sites and whether platelet integrin .alpha.(IIb).beta.3 is implicated. Displacement experiments showed that 125I-LDL binding to intact resting platelets was inhibited with the same apparent affinity by both unlabeled LDL and apolipoprotein(a)- free lipoprotein particles [Lp(a)], an LDL-like particle prepared from Lp(a)]. Hill coefficients for displacement curves suggested that a single set of binding sites was involved. In contrast, both native and oxidized Lp(a) particles were unable to inhibit platelet LDL binding. Furthermore, platelets bound 125I-Lp(a)- particles to a class of saturable binding sites numbering approximately 1958.+-.235 binding sites per platelet with a dissociation constant (K(d) of 48.3.+-.12 x 10-9 mol/L. These values were similar to those obtained for LDL. In contrast to Lp(a), evidence indicates that platelet integrin .alpha.(IIb).beta.3 was not involved in the interaction of LDL and intact resting platelets. First, specific ligands for platelet integrin .alpha.(IIb).beta.3, such as **fibrinogen**, vitronectin, and fibronectin, were unable to inhibit the binding of LDL to intact resting platelets. Second, similar LDL binding characteristics (K(d) and B(max) values) were found in platelets from control subjects and patients with type I and type II Glanzmann's thrombasthenia, characterized by total and partial lack of GPIIb-IIIa and **fibrinogen**, respectively. Third, polyclonal **antibodies** against the GPIIb- IIIa complex (edu-3 and 5B12), human antiserums against platelet alloantigens (anti-Bak(a/B) and anti-PL(A1/2), anti-integrin subunits (anti-.alpha.)(v) and anti-.beta.3, and a wide panel of monoclonal **antibodies** (mAbs) against well- known epitopes of GPIIb (M3, M4, M5, M6, and M95-2b) and GPIIIa (P23-7, P33, P37, P40 and P97) did not affect platelet LDL binding. Finally, in contrast to the proaggregatory effect of native and **oxidized LDL**, both native and oxidized Lp(a) particles caused a significant dose-dependent decrease of collagen-induced platelet aggregation. In conclusion, we demonstrate that neither the GPIIb-IIIa complex nor GPIIb and GPIIIa individually are membrane binding proteins for LDL on intact resting platelets. Lp(a) particles do not interact with platelet LDL binding sites, and their biological response is clearly different from that of LDL.

slightly reduced the expression of the intercellular adhesion molecule I (ICAM-1). In contrast, **ox-LDL** treatment upregulated ICAM-1 expression and had no significant effect on endothelial TF activity. Neither homocysteine nor **Ox-LDL** affected surface expression of the alpha(v)beta3 integrin. The homocysteine-induced enhancement in platelet adhesion was almost completely abolished by blockade of the EC TF activity by a polyclonal **antibody**. The enhancing effect of homocysteine was also greatly reduced by inhibition of the EC alpha(v)beta3 integrin, but was not affected by blockade of EC ICAM-1. On the other hand, **ox-LDL**-induced enhancement in platelet - EC adhesion was greatly inhibited by blocking ICAM-1 or alpha(v)beta3, but remained unaffected by inhibition of TF activity. Preincubation of platelets with the glycoprotein IIb-IIIa (GPIIb-IIIa) antagonist Reo-Pro has virtually abolished the enhancing effect of both homocysteine and **ox-LDL**. AB The modification of tyrosine residues in proteins to 3-nitrotyrosine by peroxynitrite or other potential nitrating agents has been detected in biological systems that are subject to oxidative stress. A convenient semi-quantitative method has been developed to assay nitrated proteins in biological fluids and homogenates using a competitive ELISA developed in our laboratory. This assay selectivity detected 3-nitro-l-tyrosine residues in a variety of peroxynitrite-treated proteins (BSA, human serum albumin (HSA), alphal-antiprotease inhibitor, pepsinogen and **fibrinogen**) and also in a nitrated peptide, but had a low affinity for free 3-nitro-L-tyrosine and 3-chloro-L-tyrosine. The IC50 values for the inhibition of **antibody** binding by different nitrated proteins were in the range 5-100 nM, suggesting that the **antibody** discriminated between nitrotyrosine residues in different environments. The presence of nitrotyrosine in plasma proteins was detected by Western blot analysis and quantified by the ELISA. A concentration of 0. 12+/-0.01 microM nitro-BSA equivalents was measured in the proteins of normal plasma

AB It has been suggested that the **fibrinogen** receptor (glycoprotein [GP] IIb-IIIa or platelet integrin alpha IIb beta 3) could be the binding site for low-density lipoprotein (LDL); however, recent data do not support this. Furthermore, GPIIb and not the GPIIb-IIIa complex is the main binding protein for lipoprotein(a) [Lp(a)]. In the present study, we have investigated the interaction between Lp(a) particles and platelet LDL binding sites and whether platelet integrin alpha IIb beta 3 is implicated. Displacement experiments showed that 125I-LDL binding to intact resting platelets was inhibited with the same apparent affinity by both unlabeled LDL and apolipoprotein(a)-free lipoprotein particles [Lp(a)-, an LDL-like particle prepared from Lp(a)]. Hill coefficients for displacement curves suggested that a single set of binding sites was involved. In contrast, both native and oxidized Lp(a) particles were unable to inhibit platelet LDL binding. Furthermore, platelets bound 125I-Lp(a)- particles to a class of saturable binding sites numbering approximately 1958 +/- 235 binding sites per platelet with a dissociation constant (Kd) of 48.3 +/- 12 x 10(-9) mol/L. These values were similar to those obtained for LDL. In contrast to Lp(a), evidence indicates that platelet integrin alpha IIb beta 3 was not involved in the interaction of LDL and intact resting platelets. First, specific ligands for platelet integrin alpha IIb beta 3, such as **fibrinogen**, vitronectin, and fibronectin, were unable to inhibit the binding of LDL to intact resting platelets. Second, similar LDL binding characteristics (Kd and Bmax values) were found in platelets from control subjects and patients with type I and type II Glanzmann's thrombasthenia, characterized by total and partial lack of GPIIb-IIIa and **fibrinogen**, respectively. Third, polyclonal **antibodies** against the GPIIb-IIIa complex (edu-3 and 5B12), human antiserums against platelet alloantigens (anti-Baka/B and anti-PLA1/2), anti-integrin subunits (anti-alpha v and anti-beta 3), and a wide panel of monoclonal **antibodies** (mAbs) against well-known epitopes of GPIIb (M3, M4, M5, M6, and M95-2b) and GPIIIa (P23-7, P33, P37, P40, and P97) did not affect platelet LDL binding. Finally, in contrast to the proaggregatory effect of native and **oxidized LDL**, both native and oxidized Lp(a) particles caused a significant dose-dependent decrease of collagen-induced platelet aggregation. In conclusion, we demonstrate that neither the GPIIb-IIIa complex nor GPIIb and GPIIIa individually are membrane binding proteins for LDL on intact resting platelets. Lp(a) particles do not interact with platelet LDL binding sites, and their biological response is clearly different from that of LDL.
